Domain 2

Buy together, pay wholesale.

Beli sama-sama, harga borong.

An Orbyte module for Malaysian micro food businesses.

The Problem

buying together is too much work

- Owners chase supplier quotes and payments through WhatsApp.
- Group buying adds manual tallies, bill splitting and delivery coordination.
- Mistakes create shortages, overpayments and disputes.
- Nearby competitors need privacy, not shared purchasing records.

Small, recurring orders miss wholesale quantity tiers.

Save a usual list; receive a ready-to-pay weekly basket.

Our Solution

one weekly approval

- **Pool demand through recurring Kongsi rounds**
- **BeliKongsi replaces one consolidated supplier order.**
- **Choose pickup or paid doorstep delivery.**
- **Show all-in prices and refund price differences to the shop's balance.**

One connected journey, from restock to receipt

01 Trigger: the weekly schedule creates a draft basket.

02 Connected data: usual lists, price tiers, quantities and delivery choices.

03 Decision: fixed rules calculate eligibility, final prices and refunds.

04 Human approval: owner pays, Ops approves, supplier confirms.

05 Visible outcome: goods delivered or refunded, savings verified, actions logged.

Technical approach: a modular, auditable platform

- Interface: Next.js, React and TypeScript; mobile-first role screens.
- Application services: baskets, rounds, orders, fulfilment and claims.
- Kongsi Engine: shared, deterministic pricing and allocation rules.
- Data: PostgreSQL on Supabase, accessed through Prisma.

Adapters: AI, payments, logistics, storage and scheduling.

Proposed Orbyte fit: shared identity, permissions, approvals and notifications.

AI reads.
Rules decide.
People approve.

- Gemini converts pasted WhatsApp orders into draft basket lines.

  A person reviews the draft before it becomes an usual list.

- Fixed rules—not AI—calculate prices, refunds and approvals.

  Owners approve spending; Ops approves supplier orders.

- Staff receive delivery tasks without price or balance data.

  Shops remain anonymous to other shops and suppliers.

Trust is built into the transaction

- Use integer sen for money calculations.
- Use idempotency and transaction controls to prevent duplicate actions.
- Test pricing invariants, refund scenarios and the end-to-end journey.
- Record state changes, ledger entries and activity logs together.
- Maintain a tamper-evident activity log and role-based access.
- **Hackathon scope: synthetic data and simulated payments and logistics.**

Expected impact : less admin, measurable net savings

- Measure net RM saved after fees, shipping and delivery — not headline discounts.
- Track basket approval time, repeat use, fulfilment accuracy and refund completion.
- Support **SDG 8**: productivity and micro-enterprise growth;
  SDG 9: connect small businesses to supplier value chains;
  SDG 10: access to wholesale pricing.

Owners: less weekly coordination and access to pooled buying power.

Suppliers: fewer fragmented orders and more predictable consolidated demand.

Prove one complete weekly restocking cycle

- Build the core journey: usual list → basket → round → supplier order → delivery → savings.
- Validate usability with 3–5 micro F&B owners or managers.
- Compare delivered cost with each shop's usual-price baseline.
- Keep real payments and logistics integration outside the hackathon demo.
- Success: less coordination, transparent prices, and every paid unit delivered or refunded.

Buy together. Spend less time organising.
